

Center correlation moves in opposite directions across the 2x2, and the two similarity axes act almost separately

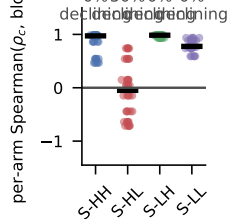

(a) within-stream center correlation, $\gamma_0=3$

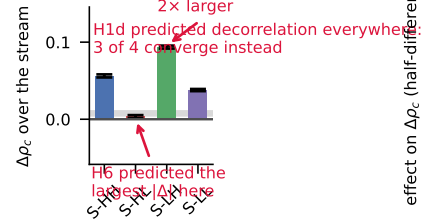

(b) the ordering is a rich-regime effect

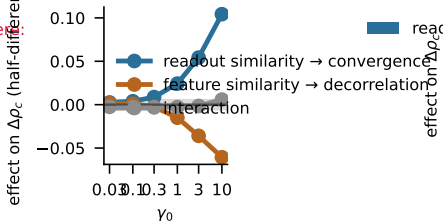

(c) is the movement progressive? (bar = median)

(d) H1d and H6 both fail ($\gamma_0=3$)

(e) richness sets the gain, the 2x2 sets the sign

(f) both main effects survive 4x load ($\gamma_0=3$)
